# TODAY'S Menu

## Lecture 1

- Units and kinematics
- Cross section & collider luminosity
- $e^+e^-$  vs hadronic colliders
- How do we "see" particles?

# Measuring particles

- Particles are characterized by
  - ✓ **Mass** [Unit: eV/c<sup>2</sup> or eV]
  - ✓ **Charge** [Unit: e]
  - ✓ **Energy** [Unit: eV]
  - ✓ **Momentum** [Unit: eV/c or eV]
  - ✓ (+ spin, lifetime, ...)

Particle identification via measurement of:

e.g. (E, p, Q) or (p,  $\beta$ , Q)  
(p, m, Q) ...

- ... and move at **relativistic speed** (here in “natural” unit:  $\hbar = c = 1$ )

$$\beta = \frac{v}{c} \quad \gamma = \frac{1}{\sqrt{1 - \beta^2}}$$

$$l = \frac{l_0}{\gamma} \quad \text{length contraction}$$

$$t = t_0 \gamma \quad \text{time dilatation}$$

$$E^2 = \vec{p}^2 + m^2$$
$$E = m\gamma \quad \vec{p} = m\gamma\vec{\beta}$$
$$\vec{\beta} = \frac{\vec{p}}{E}$$

# Center of mass energy

- In the **center of mass frame** the total momentum is 0
- In **laboratory frame** center of mass energy can be computed as:

$$E_{\text{cm}} = \sqrt{s} = \sqrt{\left(\sum E_i\right)^2 - \left(\sum \vec{p}_i\right)^2}$$

Hint: it can be computed as the “length” of the total four-momentum, that is invariant:

$$p = (E, \vec{p}) \quad \sqrt{p \cdot p}$$

What is the “length” of a the four-momentum of a particle?

# Invariant mass

$$M = \sqrt{\left(\sum E_i\right)^2 - \left(\sum \vec{p}_i\right)^2}$$

# Fixed target vs. collider

How much energy should a fixed target experiment have to equal the center of mass energy of two colliding beam?

$$E_{\text{fix}} = 2 \frac{E_{\text{col}}^2}{m} - m$$

# Interaction cross section

Flux  $\Phi = \frac{1}{S} \frac{dN_i}{dt}$   $[L^{-2} t^{-1}]$

Reactions per unit of time  $\frac{dN_{\text{reac}}}{dt} = \Phi \overbrace{\sigma N_{\text{target}} dx}^{\text{area obscured by target particle}}$   $[t^{-1}]$

$[L^{-2} t^{-1}]$   $[?]$   $[L^{-1}]$   $[L]$

Reaction rate per target particle  $W_{if} = \Phi \sigma$   $[t^{-1}]$

Cross section per target particle  $\sigma = \frac{W_{if}}{\Phi}$   $[L^2]$  = reaction rate per unit of flux

$1b = 10^{-28} \text{ m}^2$  (roughly the area of a nucleus with  $A = 100$ )

# LHC

pp collider (2008-present)

$\sqrt{s} = 7-14 \text{ GeV}$

# Cross-sections at LHC

# Why accelerating and colliding particles?

Aren't natural radioactive processes enough? What about cosmic rays?

High energy

$$E = mc^2$$

- Probe smaller scale
- Produce heavier particles

Large number of collisions

$$N = \mathcal{L} \cdot \sigma$$

- Detect rare processes
- Precision measurements

# Luminosity

Number of events  
in unit of time

$$N = \mathcal{L} \cdot \sigma$$

$[\text{t}^{-1}]$

?

$[\text{L}^{-2} \text{t}^{-1}]$

$10^{34} \text{ cm}^{-2} \text{ s}^{-1}$

$[\text{L}^2]$

$\sigma(\text{pp} \rightarrow \text{H}+\text{X}) \sim 20 \text{ pb}$

In a collider ring...

$$\mathcal{L} = \frac{1}{4\pi} \frac{fkN_1N_2}{\sigma_x\sigma_y}$$

Current

Beam sizes (RMS)

# About the inner life of a proton

- **protons have substructures**

- ✓ partons = quarks & gluons
- ✓ 3 valence (colored) quarks bound by gluons
- ✓ Gluons (colored) have self-interactions
- ✓ Virtual quark pairs can pop-up (sea-quark)
- ✓  $p$  momentum shared among constituents
  - described by  $p$  structure functions

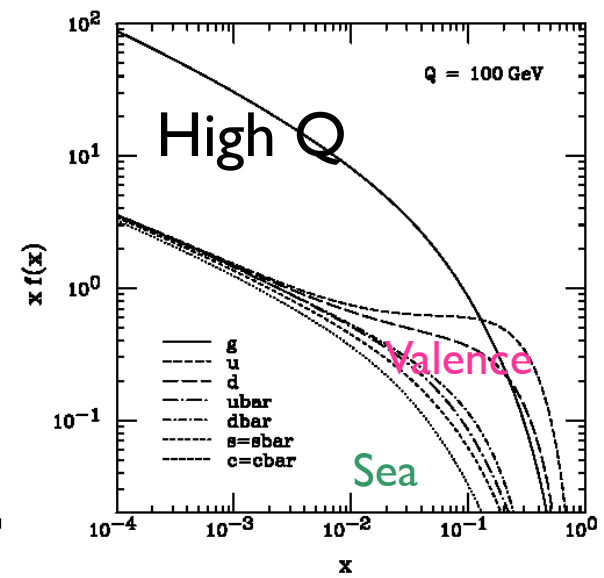

- **Parton energy not 'monochromatic'**

- ✓ Parton Distribution Function
  - PDF =  $q(x, Q^2)$ ,  $q = u, d, s, \dots, g$

- **Kinematic variables**

- ✓ Bjorken- $x$ : fraction of the proton momentum carried by struck parton
  - $x = p_{parton} / p_{proton}$
- ✓  $Q^2$ : 4-momentum<sup>2</sup> transfer

# $e^+e^-$ vs. hadron collider

$$\sqrt{\hat{s}} = \sqrt{x_a x_b s}$$

$$\sigma = \sum_{a,b} \int dx_a dx_b f_a(x, Q^2) f_b(x, Q^2) \hat{\sigma}_{ab}(x_a, x_b)$$

to produce a particle with mass  $M = 100 \text{ GeV}$

$$\sqrt{\hat{s}} = 100 \text{ GeV}$$

$$\sqrt{s} = 14 \text{ TeV} \rightarrow x = 0.007$$

$$\sqrt{s} = 5 \text{ TeV} \rightarrow x = 0.36$$

# $e^+e^-$ vs. hadron collider

## • $e^+e^-$ collider

- ✓ no internal structure
- ✓  $E_{\text{collision}} = 2 E_{\text{beam}}$
- ✓ Pros
  - Probe precise mass
    - Precision measurements
  - Clean!
- ✓ Cons
  - Only one  $E_{\text{collision}}$  at a time
  - limited by synchrotron radiation

## • Hadronic collider

- ✓ quarks + gluons (PDF)
- ✓  $E_{\text{collision}} < 2 E_{\text{beam}}$
- ✓ Pros
  - Scan different masses
    - Discovery machine
- ✓ Cons
  - $E_{\text{collision}}$  not known
  - Dirty! several collisions on top of interesting one (pileup)

# ALEPH @ LEP

# ATLAS @ LHC

# $Z \rightarrow \mu\mu$ event with 25 reconstructed vertices

April 15<sup>th</sup>, 2012

~5 cm

# How do we “see” particles?

# How do we “see” particles?

- Beam Pipe (center)
- Tracking Chamber
- Magnet Coil
- E-M Calorimeter
- Hadron Calorimeter
- Magnetized Iron
- Muon Chambers

# Magnetic spectrometer

- A system to measure (charged) particle momentum
- Tracking device + magnetic field

# Magnetic spectrometer

Charged particle in  
magnetic field

$$\frac{d\vec{p}}{dt} = q\vec{\beta} \times \vec{B}$$

If the field is constant and we neglect presence of matter, **momentum magnitude is constant** with time, **trajectory is helical**

$$p[\text{GeV}] = 0.3B[\text{T}]\rho[\text{m}]$$

Actual trajectory differ from exact helix because of:

- **magnetic field inhomogeneity**
- **particle energy loss** (ionization, multiple scattering)

# Momentum measurement

$s$  = sagitta

$l$  = chord

$\rho$  = radius

$$\rho \simeq \frac{l^2}{8s} \quad p = 0.3 \frac{Bl^2}{8s}$$

$$\left| \frac{\delta p}{p} \right| = \left| \frac{\delta s}{s} \right|$$

*smaller for larger number of points*      *measurement error (RMS)*

Momentum resolution due to measurement error

$$\left| \frac{\delta p}{p} \right| = A_N \underbrace{\frac{\epsilon}{L^2}}_{\text{projected track length in magnetic field}} \underbrace{\frac{p}{0.3B}}_{\text{resolution is improved faster by increasing } L \text{ then } B}$$

*Momentum resolution gets worse for larger momenta*

*resolution is improved faster by increasing  $L$  then  $B$*

# Hadronic showers

## Shower development:

1.  $p + \text{Nucleus} \rightarrow \text{Pions} + N^* + \dots$
2. Secondary particles ...  
undergo further inelastic collisions until they fall below pion production threshold
3. Sequential decays ...  
 $\pi^0 \rightarrow \gamma\gamma$ : yields electromagnetic shower  
 Fission fragments  $\rightarrow \beta$ -decay,  $\gamma$ -decay  
 Neutron capture  $\rightarrow$  fission  
 Spallation ...

Mean number of secondaries:  $\sim \ln E$

Typical transverse momentum:  $p_t \sim 350 \text{ MeV}/c$

Substantial electromagnetic fraction

$$f_{em} \sim \ln E$$

[variations significant]

### Cascade energy distribution:

[Example: 5 GeV proton in lead-scintillator calorimeter]

Ionization energy of charged particles ( $p, \pi, \mu$ )	1980 MeV [40%]
Electromagnetic shower ( $\pi^0, \eta^0, e$ )	760 MeV [15%]
Neutrons	520 MeV [10%]
Photons from nuclear de-excitation	310 MeV [ 6%]
Non-detectable energy (nuclear binding, neutrinos)	1430 MeV [29%]
	5000 MeV [29%]

# Energy resolution in calorimeter

Energy resolution:

e.g. inhomogeneities  
shower leakage

e.g. electronic noise  
sampling fraction variations

$$\frac{\sigma_E}{E} = \frac{A}{\sqrt{E}} \oplus B \oplus \frac{C}{E}$$

Fluctuations:

- Sampling fluctuations
- Leakage fluctuations
- Fluctuations of electromagnetic fraction
- Nuclear excitations, fission, binding energy fluctuations ...
- Heavily ionizing particles

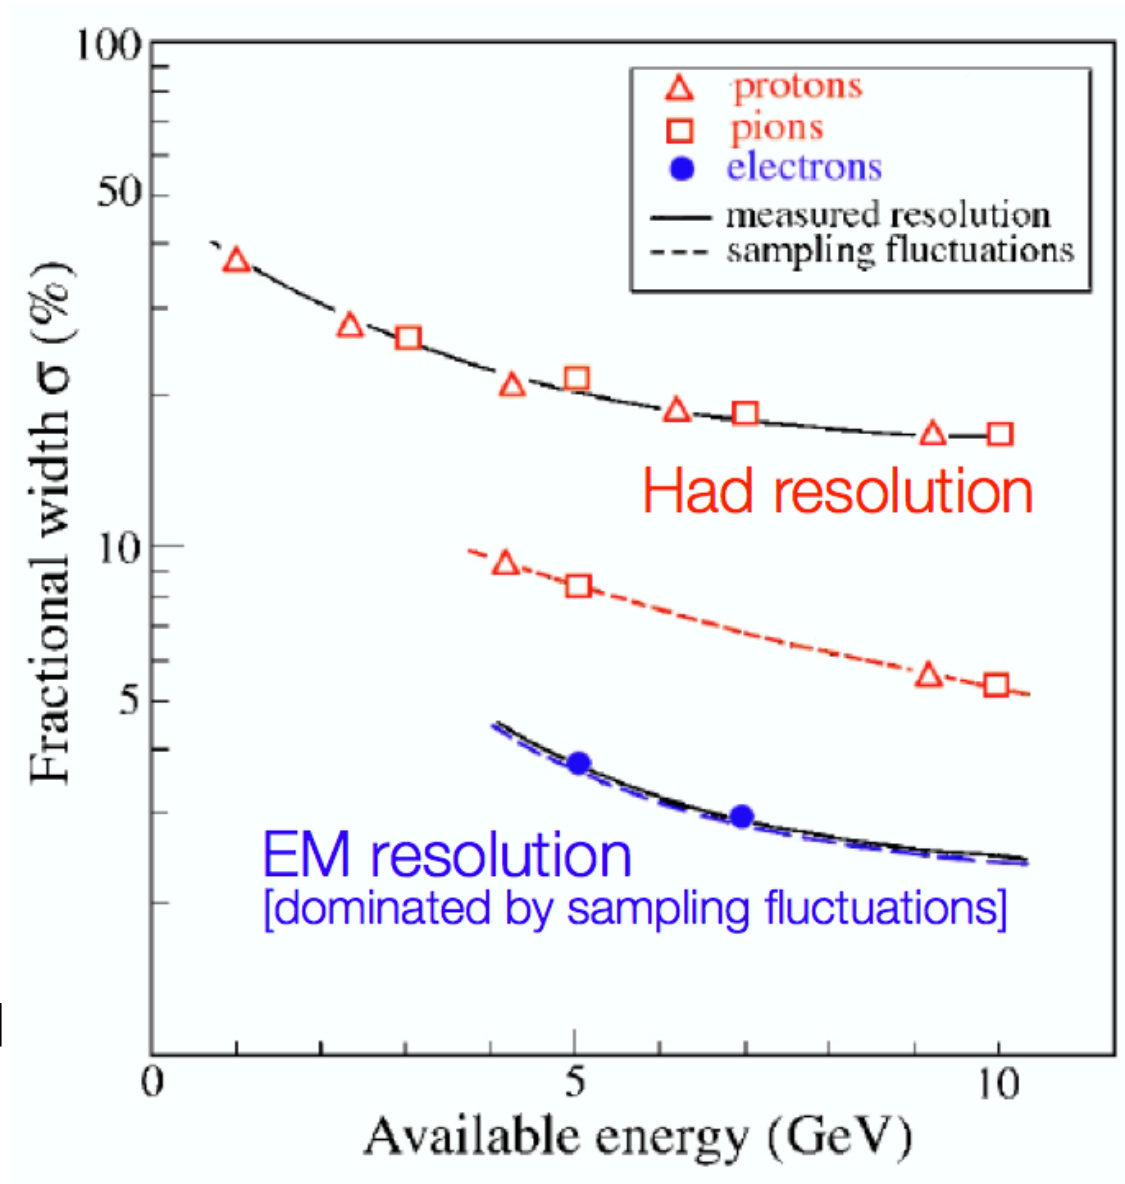

Typical:

A: 0.5 – 1.0 [Record:0.35]

B: 0.03 – 0.05

C: few %

# Resolution: EM vs. HAD

Sampling fluctuations only minor contribution to hadronic energy resolution

[AFM Collaboration]

# Particle identification with tracker and EM calo

# Particle identification with EM and HAD calos

# A few words on QCD

- QCD (strong) interactions are carried out by massless spin-1 particles called gluons
  - ✓ Gluons are massless
    - Long range interaction
  - ✓ Gluons couple to color charges
  - ✓ Gluons have color themselves
    - They can couple to other gluons

- **Principle of asymptotic freedom**

- ✓ At short distances strong interactions are weak
  - Quarks and gluons are essentially free particles
  - Perturbative regime (can calculate!)
- ✓ At large distances, higher-order diagrams dominate
  - Interaction is very strong
  - Perturbative regime fails, have to resort to effective models

quark-quark effective potential

$$V_s = -\frac{4}{3} \frac{\alpha_s}{r} + kr$$

$\underbrace{\hspace{10em}}$   $\underbrace{\hspace{5em}}$   
single gluon exchange    confinement

# Confinement, hadronization, jets

# Neutrino (and other invisible particles) at colliders

- Interaction length  $\lambda_{\text{int}} = A / (\rho \sigma N_A)$
- Cross section  $\sigma \sim 10^{-38} \text{ cm}^2 \times E [\text{GeV}]$ 
  - ✓ This means 10 GeV neutrino can pass through more than a million km of rock
- Neutrinos are usually detected in HEP experiments through *missing (transverse) energy*

- Missing energy resolution depends on
  - ✓ Detector acceptance
  - ✓ Detector noise and resolution (e.g. calorimeters)

*“That’s all Folks!”*

# HEP, SI and “natural” units

Quantity	HEP units	SI units
length	1 fm	$10^{-15}$ m
charge	e	$1.602 \cdot 10^{-19}$ C
energy	1 GeV	$1.602 \times 10^{-10}$ J
mass	1 GeV/c <sup>2</sup>	$1.78 \times 10^{-27}$ kg
$\hbar = h/2\pi$	$6.588 \times 10^{-25}$ GeV s	$1.055 \times 10^{-34}$ Js
c	$2.988 \times 10^{23}$ fm/s	$2.988 \times 10^8$ m/s
$\hbar c$	197 MeV fm	...

## “natural” units ( $\hbar = c = 1$ )

mass	1 GeV
length	1 GeV <sup>-1</sup> = 0.1973 fm
time	1 GeV <sup>-1</sup> = $6.59 \times 10^{-25}$ s

# Relativistic kinematics in a nutshell

$$E^2 = \vec{p}^2 + m^2$$

$$l = \frac{l_0}{\gamma}$$

$$E = m\gamma$$

$$t = t_0\gamma$$

$$\vec{p} = m\gamma\vec{\beta}$$

$$\vec{\beta} = \frac{\vec{p}}{E}$$

# Cross section: magnitude and units

Standard

cross section unit:

$$[\sigma] = \text{mb}$$

with  $1 \text{ mb} = 10^{-27} \text{ cm}^2$

or in

natural units:

$$[\sigma] = \text{GeV}^{-2}$$

with  $1 \text{ GeV}^{-2} = 0.389 \text{ mb}$   
 $1 \text{ mb} = 2.57 \text{ GeV}^{-2}$

Estimating the  
proton-proton cross section:

---

using:  $\hbar c = 0.1973 \text{ GeV fm}$   
 $(\hbar c)^2 = 0.389 \text{ GeV}^2 \text{ mb}$

Proton radius:  $R = 0.8 \text{ fm}$   
Strong interactions happens up to  $b = 2R$

$$\begin{aligned}\sigma &= \pi (2R)^2 = \pi \cdot 1.6^2 \text{ fm}^2 \\ &= \pi \cdot 1.6^2 \cdot 10^{-26} \text{ cm}^2 \\ &= \pi \cdot 1.6^2 \cdot 10 \text{ mb} \\ &= 80 \text{ mb}\end{aligned}$$

# Proton-proton scattering cross-section

http://pdg.lbl.gov/

# Synchrotron radiation

energy lost per revolution

$$\Delta E = \frac{4\pi}{3} \frac{1}{4\pi\epsilon_0} \left( \frac{e^3 \beta^3 \gamma^4}{R} \right)$$

electrons vs. protons

$$\frac{\Delta E_e}{\Delta E_p} \simeq \left( \frac{m_p}{m_e} \right)^4$$

It's easier to accelerate protons to higher energies, but protons are fundamentals...

# CERN accelerator complex

# Interaction mode recap...

- electrically charged
- ionization ( $dE/dx$ )
- electromagnetic shower

- electrically charged
- ionization ( $dE/dx$ )
- can emit photons
  - ✓ electromagnetic shower induced by emitted photon

- electrically neutral
- pair production
  - ✓  $E > 1 \text{ MeV}$
- electromagnetic shower

- produce hadron(s) jets via QCD hadronization process

# Hadronic vs. EM showers

## Comparison

hadronic vs. electromagnetic shower ...

[Simulated air showers]

# Homogeneous calorimeters

- ★ In a homogeneous calorimeter the whole detector volume is filled by a high-density material which simultaneously serves as absorber as well as as active medium ...

Signal	Material
Scintillation light	BGO, BaF <sub>2</sub> , CeF <sub>3</sub> , ...
Cherenkov light	Lead Glass
Ionization signal	Liquid noble gases (Ar, Kr, Xe)

- ★ Advantage: homogenous calorimeters provide optimal energy resolution
- ★ Disadvantage: very expensive
- ★ Homogenous calorimeters are exclusively used for electromagnetic calorimeter, i.e. energy measurement of electrons and photons

# Sampling calorimeters

## Scheme of a sandwich calorimeter

Principle:

Alternating layers of absorber and active material [sandwich calorimeter]

Absorber materials:  
[high density]

Iron (Fe)

Lead (Pb)

Uranium (U)  
[For compensation ...]

Active materials:

Plastic scintillator

Silicon detectors

Liquid ionization chamber

Gas detectors

Electromagnetic shower

# A typical HEP calorimetry system

Typical Calorimeter: two components ...

Electromagnetic (EM) +  
Hadronic section (Had) ...

Different setups chosen for  
optimal energy resolution ...

But:

Hadronic energy measured in  
both parts of calorimeter ...

Needs careful consideration of  
different response ...

Schematic of a  
typical HEP calorimeter

Electrons  
Photons

Taus  
Hadrons

Jets

# B-tagging

- When a b quark is produced, the associated jet will very likely contain at least one B meson or hadron
- B mesons/hadrons have relatively long lifetime
  - ✓ They will travel away from collision point before decaying
- Identifying a secondary decay vertex in a jet allow to tag its quark content
- Similar procedure for c quark...

# top quark

- Top quark has a mean lifetime of  $5 \times 10^{-25}$  s, shorter than time scale at which QCD acts: no time to hadronize!
  - ✓ It decays as  $t \rightarrow Wb$
- Events with top quarks are very rich in (b) jets...

- LHC is a "top factory"!
- 5 millions of  $t\bar{t}$  pairs
  - ~100000 in Tevatron in 20 years

# Tau

- Tau are heavy enough that they can decay in several final states
  - ✓ Several of them with hadrons
  - ✓ Sometimes neutral hadrons
- Lifetime = 0.29 ps
  - ✓ 10 GeV tau flies ~ 0.5 mm
  - ✓ Typically too short to be directly seen in the detectors
- Tau needs to be identified by their decay products
- Accurate vertex detectors can detect that they do not come exactly from the interaction point
