Neutrino interactions

Neutron detection only via weak interaction ...

Possible reactions:

Charged Current Reactions:

$$\nu_e + n \rightarrow e^- + p$$

$$\bar{\nu}_e + p \rightarrow e^+ + n$$

$$\nu_\mu + n \rightarrow \mu^- + p$$

$$\bar{\nu}_\mu + p \rightarrow \mu^+ + n$$

$$\nu_\tau + n \rightarrow \tau^- + p$$

$$\bar{\nu}_\tau + p \rightarrow \tau^+ + n$$

...

$$\bar{\nu}_e + e^- \rightarrow \mu^- + \bar{\nu}_\mu$$

$$\bar{\nu}_e + e^- \rightarrow \tau^- + \bar{\nu}_\tau$$

Neutral Current Reactions:

$$\nu_e + e^- \rightarrow \nu_e + e^-$$

$$\nu_\mu + e^- \rightarrow \nu_\mu + e^-$$

$$\nu_\tau + e^- \rightarrow \nu_\tau + e^-$$

Remark:

Neutral Current ν N-interactions not usable due to small energy transfer

Neutrino nucleon x-Section:
[examples]

10 GeV neutrinos: $\sigma = 7 \cdot 10^{-38} \text{ cm}^2/\text{nucleon}$

Interaction probability for 10 m Fe-target: $R = \sigma \cdot N_A [\text{mol}^{-1}/\text{g}] \cdot d \cdot \rho = 3.2 \cdot 10^{-10}$
with $N_A = 6.023 \cdot 10^{23} \text{ g}^{-1}$; $d = 10 \text{ m}$; $\rho = 7.6 \text{ g/cm}^3$

Solar neutrinos [100 keV]: $\sigma = 7 \cdot 10^{-45} \text{ cm}^2/\text{nucleon}$

Interaction probability for earth: $R = \sigma \cdot N_A [\text{mol}^{-1}/\text{g}] \cdot d \cdot \rho \approx 4 \cdot 10^{-14}$
with $N_A = 6.023 \cdot 10^{23} \text{ g}^{-1}$; $d = 12000 \text{ km}$; $\rho = 5.5 \text{ g/cm}^3$

Neutrino interactions: V-e

Process	Total Cross section
$\nu_\mu + e^- \rightarrow \mu^- + \nu_e$	$\frac{G_F^2 s}{\pi} \quad 1.7 \cdot 10^{-43} \left(\frac{E}{10\text{MeV}} \right) \text{cm}^2$
$\nu_e + e^- \rightarrow \nu_e + e^-$	$\frac{G_F^2 s}{4\pi} \left[(2\sin^2 \theta_W - 1)^2 + \frac{4}{3} \sin^4 \theta_W \right]$
$\bar{\nu}_e + e^- \rightarrow \bar{\nu}_e + e^-$	$\frac{G_F^2 s}{4\pi} \left[\frac{1}{3} (2\sin^2 \theta_W + 1)^2 + 4\sin^4 \theta_W \right]$
$\nu_\mu + e^- \rightarrow \nu_\mu + e^-$	$\frac{G_F^2 s}{4\pi} \left[(2\sin^2 \theta_W - 1)^2 + \frac{4}{3} \sin^4 \theta_W \right]$
$\bar{\nu}_\mu + e^- \rightarrow \bar{\nu}_\mu + e^-$	$\frac{G_F^2 s}{4\pi} \left[\frac{1}{3} (2\sin^2 \theta_W - 1)^2 + 4\sin^4 \theta_W \right]$

Neutrino interactions: V-nucleon

- Interaction happens with whole nucleon
 - ✓ Nucleon can at best undergo an *isospin* transition in case of charged current (quasi-elastic scattering)
 - ✓ In case of neutral current, scattering is perfectly elastic

Neutrino interactions: quasi-elastic ν -nucleon

Threshold is different for different neutrino flavors...

Paolo Lipari, Maurizio Lusignoli, Francesca Sartogo, "The neutrino cross section and upward going muons" <http://arxiv.org/abs/hep-ph/9411341>

$$E \ll m_n \quad \sigma(\nu n) = \sigma(\bar{\nu} p) \approx$$

$$9.75 \cdot 10^{-42} \left(\frac{E}{10 \text{ MeV}} \right)^2 \text{ cm}^2$$

$$E > 1 \text{ GeV}$$

$$\sigma/E \sim \text{constant}$$

A neutrino interaction...

Another neutrino interaction...

Neutrino interaction cross sections comparison

Figure 5. Energy dependence of various neutrino reactions and corresponding event rates. ($f_{e/N} = 1$ for reactions on nucleons, $f_{e/N} = A/Z$ for reactions on electrons.)

close to thresholds...

$$\sigma \sim \frac{(s - m_\mu^2)^2}{s}$$

$$s_{lab} = 2m_e E + m_e^2$$

Neutrino interaction inclusive cross section

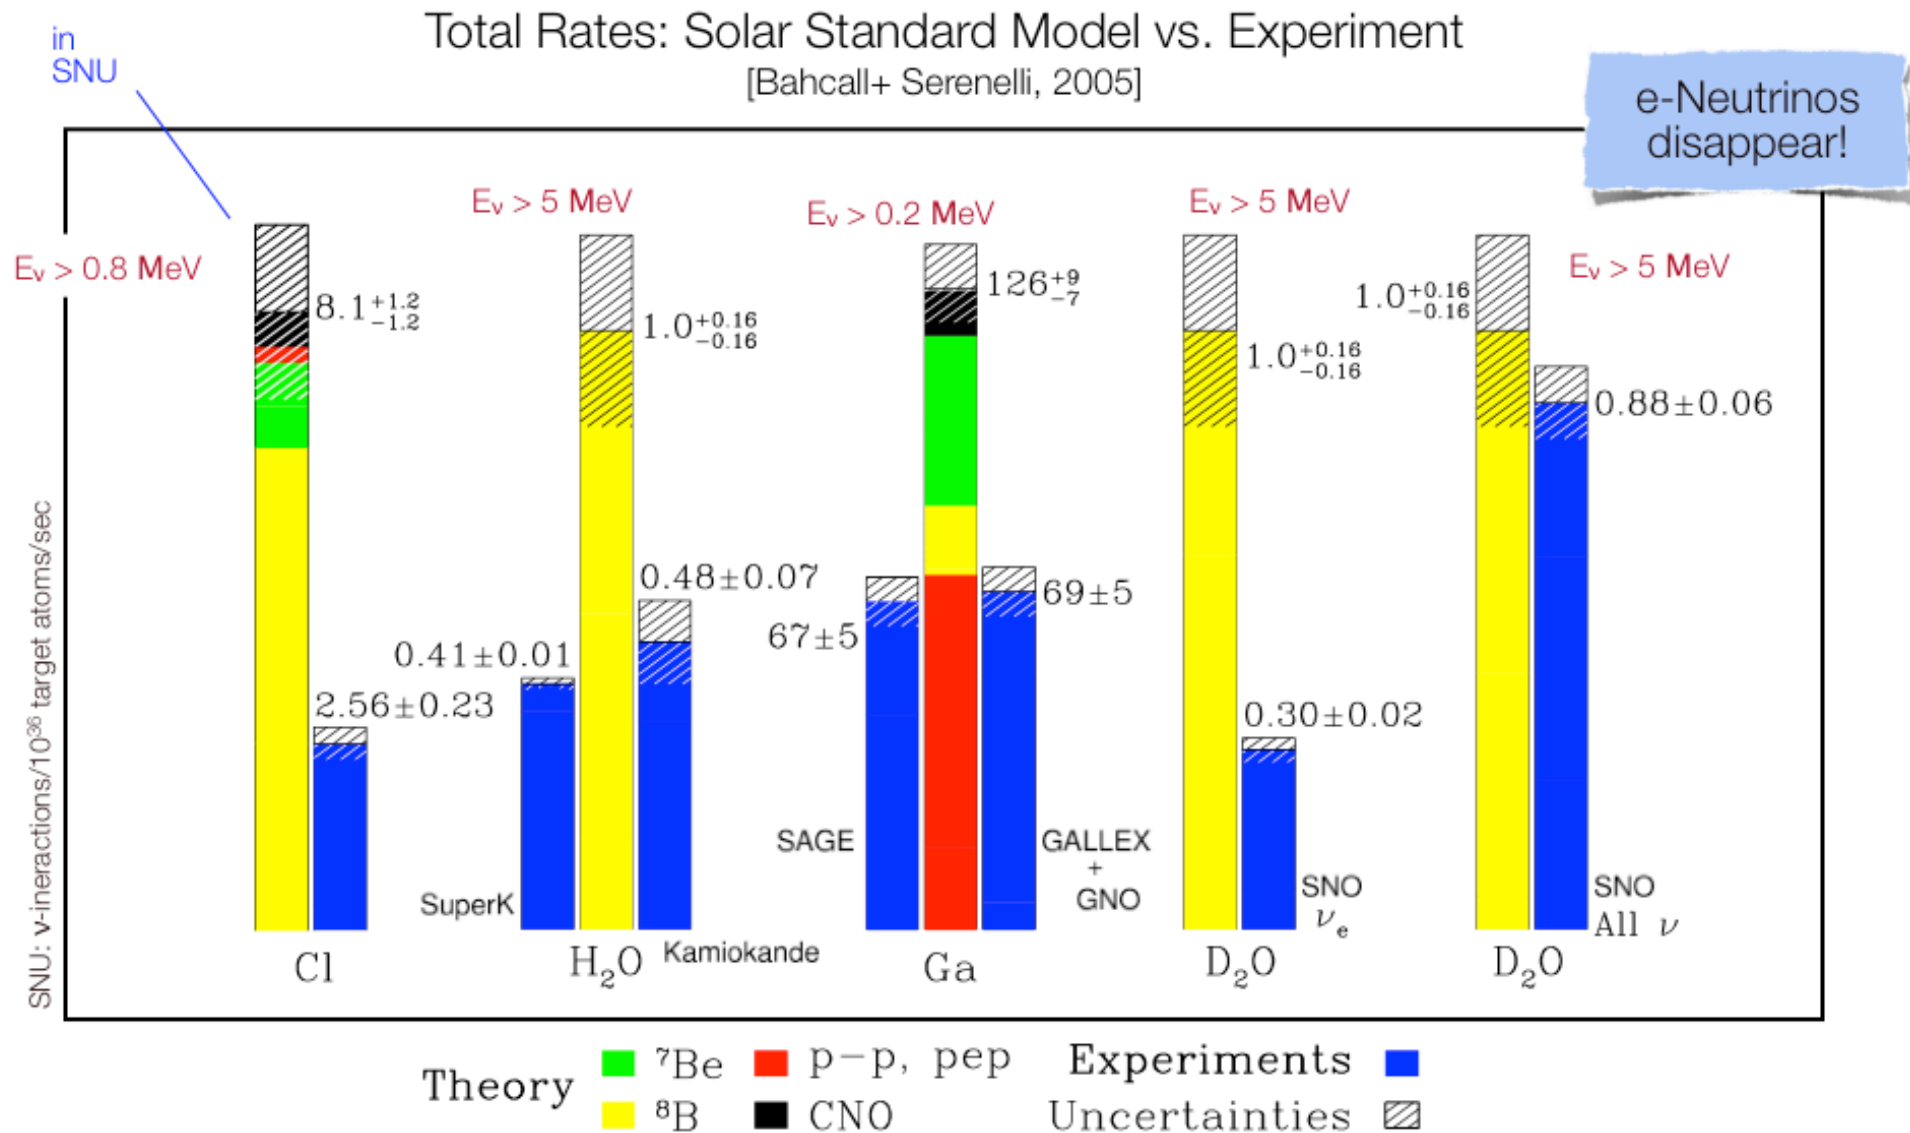

Neutrinos from the Sun

Neutrinos from the Sun

The “solar electron neutrino” problem

Neutrino oscillation

Imagine we send a neutrino on a *long* journey. Suppose neutrino is created in the pion decay

$$\pi \rightarrow \mu \nu_{\mu}$$

so that at birth it is a muon neutrino. Imagine that this neutrino interacts via W exchange in a distant detector, turning into a charged lepton. **If neutrinos have masses and leptons mix, then this charged lepton need not be a muon**, but could be, say, a tau.

- **Neutrinos have masses** \rightarrow there is some spectrum of neutrino mass eigenstates ν_i w/ mass m_{ν_i}
- **Leptons mix** \rightarrow neutrinos of definite flavor, ν_e , ν_{μ} , and ν_{τ} , are not mass eigenstates ν_i .

$$|\nu_{\alpha}\rangle = \sum_i U_{\alpha i}^* |\nu_i\rangle \quad U = \begin{array}{c} e \\ \mu \\ \tau \end{array} \begin{array}{ccc} \nu_1 & \nu_2 & \nu_3 \\ \left[\begin{array}{ccc} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} \end{array} \right] \end{array}$$

Probability of neutrino oscillation

$$P(\bar{\nu}_\alpha \rightarrow \bar{\nu}_\beta; L, E) = \delta_{\alpha\beta} - 4 \sum_{i>j} \Re (U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin^2(\Delta m_{ij}^2 \frac{L}{4E})$$

$$+ 2 \sum_{i>j} \Im (U_{\alpha i}^* U_{\beta i} U_{\alpha j} U_{\beta j}^*) \sin(\Delta m_{ij}^2 \frac{L}{2E})$$

For full calculation see for instance Boris Kayser "Neutrino Oscillation Physics" <http://arxiv.org/abs/1206.4325>

(Simplified) probability of neutrino oscillation

Let's forget the imaginary part of U (assume neutrinos and antineutrinos behave the same) and suppose only 2 flavors...

$$U = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}$$

$$\begin{aligned} P(l \rightarrow l') &= 2 \cos^2 \theta \sin^2 \theta - 2 \cos^2 \theta \sin^2 \theta \cos \frac{m_j^2 - m_k^2}{2E} L \\ &= 2 \cos^2 \theta \sin^2 \theta \left(1 - \cos \frac{m_j^2 - m_k^2}{2E} L \right) = 4 \cos^2 \theta \sin^2 \theta \sin^2 \left(\frac{m_j^2 - m_k^2}{4E} L \right) \\ &= \sin^2 2\theta \sin^2 \left(\frac{m_j^2 - m_k^2}{4E} L \right) \end{aligned}$$

(Simplified) probability of neutrino oscillation

... and calculate!

$$\frac{m_j^2 - m_k^2}{4E} L = \frac{\Delta m^2 [\text{eV}^2]}{4 \times 10^6 E [\text{MeV}] \hbar c} \frac{L}{197 \times 10^6 [\text{eV}] \times 10^{-15} [\text{m}]} \\ = 1.27 \frac{\Delta m^2 [\text{eV}^2] L [\text{m}]}{E [\text{MeV}]} = 1.27 \frac{\Delta m^2 [\text{eV}^2] L [\text{km}]}{E [\text{GeV}]}$$

Being able to observe oscillations implies **phase variation ~ 1** .

Given L and E, accessible range is thus **$\Delta m^2 [\text{eV}^2] > E [\text{GeV}] / L [\text{km}]$**

Sorgente	E	L	$\Delta m^2 [\text{eV}^2]$
Reattori	1 - 10 MeV	10 m - 100 km	
Acceleratori	0.1 - 10 GeV	10 m - 100 km	
Atmosferici	1-10 GeV	10 - 10000 km	
Solari	0.1 - 10 MeV	1.5×10^{11} m	

Nobel Prize 2002

The Nobel Prize in Physics 2002 was divided, one half jointly to Raymond Davis Jr. and Masatoshi Koshiba "*for pioneering contributions to astrophysics, in particular for the detection of cosmic neutrinos*" and the other half to Riccardo Giacconi "*for pioneering contributions to astrophysics, which have led to the discovery of cosmic X-ray sources*".

Neutrino capture:

Lifetime: 35 days

Detection of ^{37}Ar via e^- -capture [$^{37}\text{Ar}(e, \nu_e)^{37}\text{Cl}$]; $\tau \approx 35$ days
results in Auger-electron @ 2.82 keV which after
extraction is detected in proportional counter

Experimental details:

- 615 tons of C_2Cl_4
- Threshold: 814-keV threshold
- Bubble He gas through to extract Ar [every 2-3 month]
- Ar trapped in cold trap
- Proportional Counter filled with Ar gas (7% methane)
- Important: ^{37}Cl is 24% abundant.

The Homestake experiment

The Chlorine Experiment

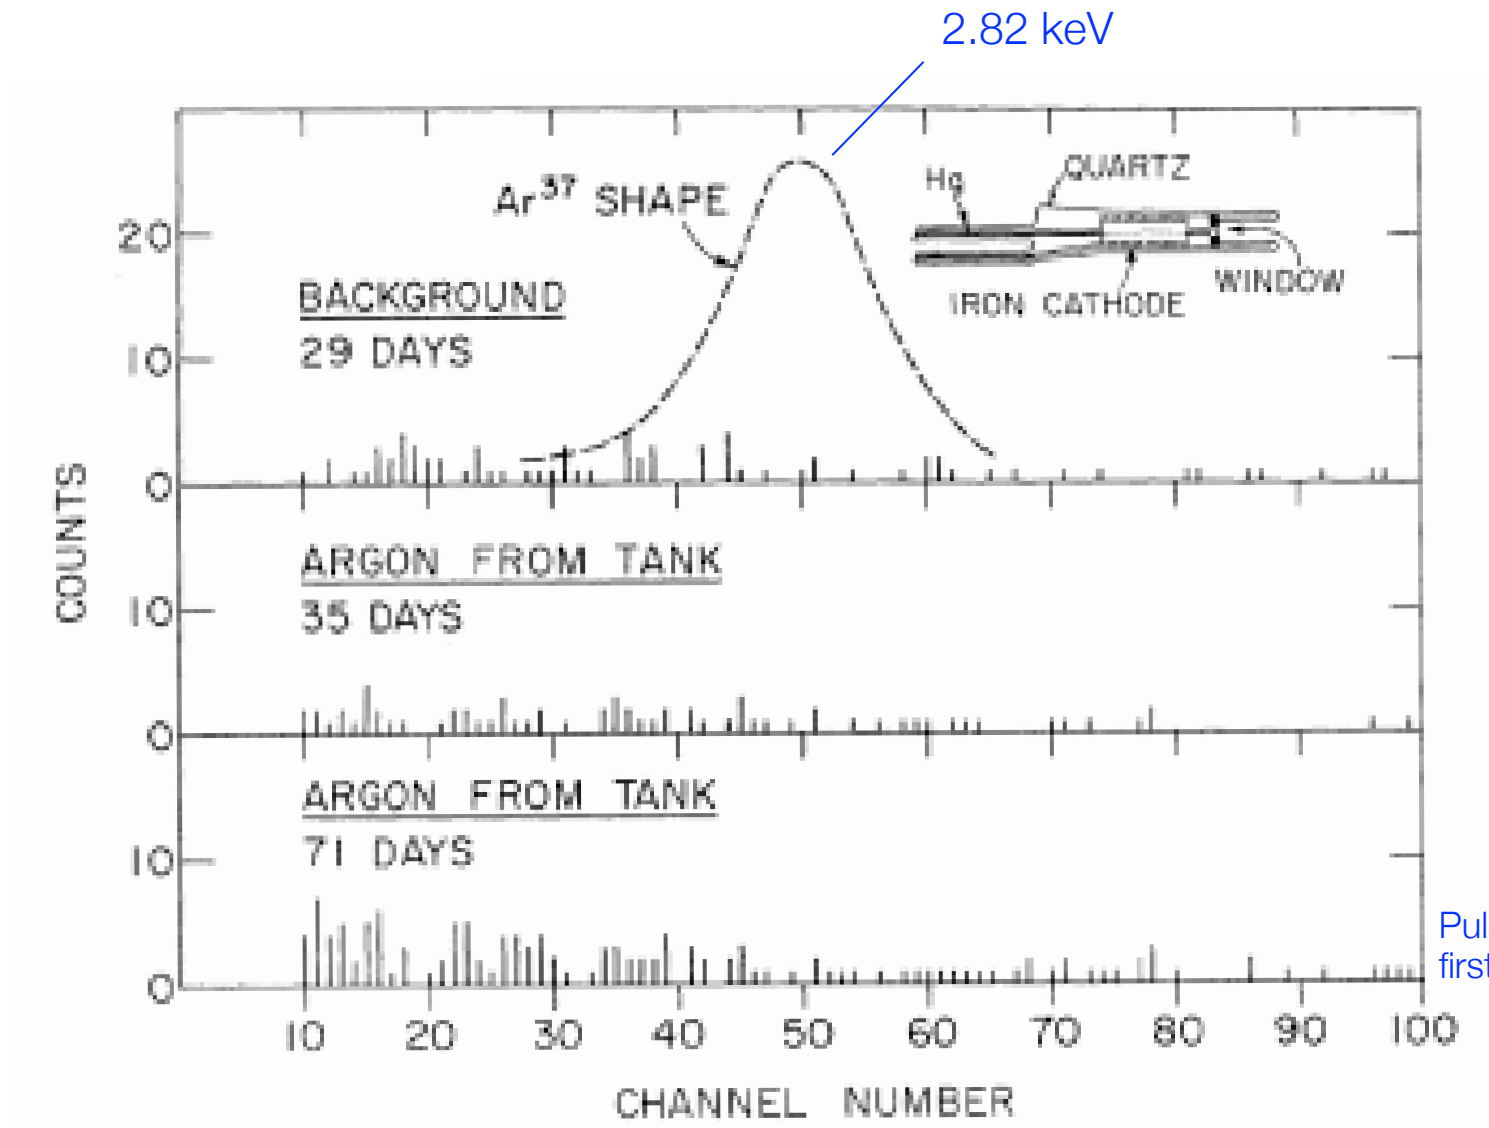

The Homestake experiment

Some *very approximate* numbers ...

- 615 tons C_2Cl_4 (Tetrachloroethelene)
- About 5×10^{29} Chlorine Atoms (^{37}Cl)
6 Atoms/Molecule
- Prediction: 8×10^{-36} ν -reactions/atom/sec
i.e.: about 60 ^{37}Ar -atoms/month;
but: half-life = 35 days \rightarrow 30 atoms/month
- Expect: 60 atoms every 2 month out of
ca. 10^{30} Tetrachloroethelene molecules
 *^{37}Ar -Extraction
Efficiency: $\sim 95\%$*
- After 25 years:
Expectation: ~ 5000 ^{37}Ar -Atoms expected
Observation: ~ 2200 ^{37}Ar -Atoms produced
 *^{37}Ar -Detection
Efficiency: $\sim 45\%$*
[875 counted; 776 after background subtraction]

The SNO experiment

The SNO experiment

The SNO experiment

More than 2 km below ground
Background: $< 100 \mu/\text{day}$

The SNO experiment

- Measurement of ν_e energy spectrum
- Weak directionality: $1 - 0.340 \cos \theta$

- Measure total ^8B ν flux from the sun
- $\sigma(\nu_e) = \sigma(\nu_\mu) = \sigma(\nu_\tau)$

- Low Statistics
- $\Sigma \phi = \phi(\nu_e) + 0.154 \phi(\nu_\mu + \nu_\tau)$
- Strong directionality:
 $\theta_e \leq 18^\circ$ ($T_e = 10 \text{ MeV}$)

The SNO experiment

Analysis strategy:

Determine size of CC, ES and NC signals via a fit of the data to probability distributions

The SNO experiment

The SNO experiment

$$\phi_{\text{CC}} = 1.76_{-0.05}^{+0.06} (\text{stat.})_{-0.09}^{+0.09} (\text{syst.}) \times 10^6 \text{ cm}^{-2} \text{ s}^{-1}$$

CNGS

TPC as neutrino detectors

<http://cds.cern.ch/record/117852/files/CERN-EP-INT-77-8.pdf>

Why LAr for neutrino detectors?

- Excellent insulator, very weakly electronegative: free electrons produced by ionization drift long distances
- Produces many electron-ion pairs: measurement of energy deposited in liquid;
- Good scintillator: measurement of energy of luminous flash produced by event, event localization
- Available in sufficient quantity

	Argon	CF ₃ Br
Nuclear collision length	53.2	49.5 cm
Absorption length	80.9	73.5 cm
dE/dx, minimum	2.11	2.3 MeV/cm
Radiation length	14	11 cm
Density	1.40	1.50 g/cm ³

ICARUS (Imaging Cosmic And Rare Underground Signals)

Hall B @ LNGS

■ Two identical modules

- $3.6 \times 3.9 \times 19.6 \approx 275 \text{ m}^3$ each
- Liquid Ar active mass: $\approx 476 \text{ t}$
- Drift length = 1.5 m (1 ms)
- HV = -75 kV E = 0.5 kV/cm
- v-drift = 1.55 mm/ μ s

■ 4 wire chambers:

- 2 chambers per module
- 3 readout wire planes per chamber, wires at $0, \pm 60^\circ$
- ≈ 54000 wires, 3 mm pitch, 3 mm plane spacing
- 20+54 PMTs, 8" \varnothing , for scintillation light detection:
 - VUV sensitive (128nm) with wave shifter (TPB)

Dark matter astronomical evidence

WIMP detection: cryogenic experiments

WIMPs = Weakly interacting massive particles ...

Dark matter particles; must be neutral, i.e. must neither interact via electromagnetic nor strong interactions; WIMPs must be heavy, i.e. non-relativistic (cold dark matter) in order to allow for galaxy formation ...

Assumed mass range: 10 GeV - 10 TeV

Mass limits dependent on cross section ...

[e.g.: $\sigma_{\chi p} = 1.6 \cdot 10^{-7}$ pb yields $m_{\text{WIMP}} > 60$ GeV]

Detection via elastic χp -scattering ...

Assume WIMP velocity: $v_\chi \approx 300$ km/s, i.e. $\beta = 10^{-3}$...

Solar system speed w.r.t. to milky way: $v = 250$ km/s

Velocity of earth moving w.r.t solar system: $v = 30$ km/s

Maximum energy transfer:

$$T_K^{\text{max}} = 2 \frac{m_\chi^2 M_K c^2}{(m_\chi + M_K)^2} \beta^2 \approx 2 M_K v_\chi^2 \quad \left[\begin{array}{l} m_\chi \gg M_K \end{array} \right]$$

$M_K = 100$ GeV
 $\rightarrow T_K^{\text{max}} \approx 100$ keV

How to detect WIMP?

Transferred energy of recoiling nuclei generally much smaller ($< 10\%$) ...
Need detector that allows nuclei detection below keV range ...

Energy resolution requires: $N_{\text{excite}} \gg 1$
i.e. $E_{\text{excite}} \ll 1 \text{ eV}$

Remember:

Gases	–	ionization energy $\approx 30 \text{ eV}$
Silicon	–	electron/hole pair creation $\approx 3 \text{ eV}$

Better possibilities:

Phonon excitation:

Maximum phonon energy in Si is 60 meV; roughly 2/3 of the energy required for electron-hole formation goes into phonon excitation ...

Superconducting detectors:

In superconductors the energy gap 2Δ is equivalent to the band gap in semiconductors; absorption of energy $> 2\Delta$ (typically 1 meV) can break up a Cooper pair ...

Cryogenic detectors:

Detect low energies
with very good resolution ...

Cryogenic detectors

Phonon Detectors ...

Assume thermal equilibrium:

Convert absorbed energy
into phonons:

$$\Delta T = E/C$$

C: heat capacity of the sample
[specific heat \times mass]

E: deposited energy

Optimal detector: low heat capacity

Example 1: Si-detector at room temperature ...

$$C_{\text{spec}} = 0.7 \text{ J/gK}; E = 1 \text{ keV}; m = 1 \text{ g} \rightarrow \Delta T = 2 \cdot 10^{-16} \text{ K}$$

Not very practical ...

Need lower specific heat and mass ...

Example 2: Si-detector at low temperature ...

$$C_{\text{spec}} \propto (T/\Theta)^3; C_{\text{spec}} = 2 \cdot 10^{-15} \text{ K}; T = 0.1 \text{ K};$$

$$E = 1 \text{ keV}; m = 15 \mu\text{g}$$

$$\rightarrow \Delta T = 0.04 \text{ K [possible!]}$$

Basic configuration
of cryogenic calorimeter

Resolution:

$$n = CT/kT = C/k$$

$$\sigma_0 = kT\sqrt{n} = \sqrt{(CkT^2)}$$

$$\sigma_E = \epsilon_{\text{Ph}}\sqrt{(E/\epsilon_{\text{Ph}})} = \sqrt{(kTE)}$$

$$\sigma = \sigma_0 + \sigma_E$$

Yields: $\sigma < 0.2 \text{ eV}$

[Si Semiconductor detector: $\sigma = 20 \text{ eV}$]

Dark matter detection overview

Dark matter detection

Example: CDMS

[Soudan Underground Lab]

5 towers each with 6 Ge/Si detectors
operated at $T \approx 20$ mK ...

Double readout:

Temperature change (Phonons)
Charge readout (Ionization)

Idea:

WIMPs (and neutrons) scatter off nuclei
Most background noise sources (γ, e) scatter off electrons
Different response to nuclear recoils than to electron recoils

[View into
CDMS Experiment](#)

Did anyone observe signs of dark matter?

- Currently (2015) 3 experiments claim evidence for potential DM signals
 - ✓ DAMA/LIBRA (Gran Sasso)
 - 9.3σ for annual modulation of single-hit events
 - 2-6 keV energy, (0.0112 ± 0.0012) counts/kg/keV/day amplitude; (144 ± 7) days phase; (0.998 ± 0.002) years period
 - ✓ CoGeNT (Soudan Underground Lab)
 - $\sim 2\sigma$ DM excess, annual modulation
 - ✓ CDMS-II (SNOLAB)
 - 3 unexplained low-energy events in Si-detector sample
 - ✓ After detector upgrade, CRESST-II no longer finds previously claimed excess
- All claimed excesses cluster in mass region of tens of GeV with cross sections between 10^{-42} and 10^{-39} cm²
- All other direct detection searches have set exclusion limits on the dark matter-nucleus cross section that contradict the claims listed above

Did anyone observe signs of dark matter?

Did anyone observe signs of dark matter?

Finding new particles that constitute dark matter would be a major breakthrough in physics. As extraordinary new findings require extraordinary evidence, the hurdles are high. Various unusual experimental results of the last decade have been interpreted in terms of dark matter, but all of them could also be the result of a misunderstood background or other effects.

M. Klasen, M. Pohl, G. Sigl

Indirect and direct search for dark matter
